Dear Editors,

We are submitting “*Three Axes of Quantum Risk: A Unified Observability Model for PQC, QKD, and Crypto-Agility*” for consideration in *EPJ Quantum Technology* as a Research article.

PQ-readiness scanners today answer one question: is the primitive quantum-resistant? Two assets that look identical under that question can have very different migration costs, and very different channel-level protections, neither of which the scanner sees. The paper treats quantum-risk posture as a three-axis problem instead, scoring each asset on algorithmic resistance, channel protection, and migration agility, then folding the three into a deadline-adjusted risk score q . We validate all three axes with reproducible studies — a Tranco-top-1k TLS survey (43.8% hybrid PQ key exchange), a controlled ETSI GS QKD 014 emulator study (13 of 13 induced link/KME transitions classified correctly), and an 11-project crypto-agility pilot (91% agreement with hand-graded ground truth) — and release the reference implementation end to end: eBPF-based TLS observation, a working ETSI GS QKD 014 collector with a Key-Management-Entity emulator, and a static crypto-agility scanner. Every artifact is open at <https://github.com/e2esolutions-tech/ree0xQ> under MIT.

Why EPJ Quantum Technology. The deployment side of quantum technology is where this work lives: the QKD axis treats channel-level quantum-secure key delivery as a measured property of an asset rather than a separate policy track, and the KME emulator lets practitioners reproduce the channel-state classification results on one Linux host with no QKD hardware. The journal’s coverage of deployed QKD networks and their operational telemetry — work we build on directly in the manuscript — makes it the natural home for a measurable, QKD-aware posture model paired with a reproducible test rig.

Submission disclosures

- The manuscript is not under consideration at any other journal. A preprint is available on Research Square.
- Both authors approved the manuscript and the CRediT contributions stated in §10.
- We declare no competing interests. E2E Solutions develops and releases the platform under MIT but derives no direct commercial revenue from the publication.
- The work was self-funded by E2E Solutions and Hacettepe University; no external grants.
